

# Can we understand the weak density scaling of the energy confinement time in W7-X ECRH plasmas?

G. Fuchert, M. Beurskens, S. Bozhenkov, F. Warmer and the W7-X team Special thanks to the Interferometer, TS, XICS, and diam. loop teams.

This work has been carried out within the framework of the EUROfusion Consortium and has received funding from the Euratom research and training programme 2014-2018 under grant agreement No 633053. The views and opinions expressed herein do not necessarily reflect those of the European Commission.

## **Motivation**

- One of the promising features of stellarators is that empirically the energy confinement time increases with density
  - A reactor needs high density for core performance (alpha-heating and coupling to ions) and envisioned exhaust concepts (high radiation, divertor pressure,...).
  - It is believed that an economically feasible reactor needs at the very least a confinement on par with the emprical scaling ISSO4, preferably 1.5 x ISSO4, see [Warmer, FST, (2015)].
- Unfortunately, W7-X is showing a weaker density scaling than ISS04, causing lower relative performance ( $\tau_E/\tau_{ISS04}$ ) as the density is increased
  - Keep in mind: The density scaling of W7-X is still positive, just not as strong as in ISS04.
  - Question: Does this mean we did something "wrong" with W7-X?
  - Peaked density profiles improve the performance above ISSO4 levels. Due to the fueling characteristics, this may, however, not be a viable reactor scenario.

$$\tau_{\rm ISS04} = 0.134a^{2.28}R^{0.64}P^{-0.61}\bar{n}_{\rm e}^{0.54}B^{0.84}t_{2/3}^{0.41}$$

# A (crude) model for global transport

- Often, the scaling of  $\tau_{\scriptscriptstyle E}$  is associated with certain transport effects
  - Examples: "ISS04 is consistent with Gyro-bohm" or "1/v-transport should result in a stronger density scaling than ISS04"
- Which physical picture lies behind such statements?
  - If we assume  $T_e = T_i = T$ ,  $W = 3/2 \cdot 2 \cdot < n > < T > V$  and that a diffusive ansatz describes transport:

$$P/S = -2\bar{n}\chi_{\text{eff}}\nabla T \approx \bar{n}\chi_{\text{eff}}\bar{T}/a$$

$$\tau_{\text{E}} = \frac{W}{P} = \frac{3}{2} \cdot \frac{2\bar{n}\bar{T}V}{P}$$

$$\tau_{\text{E}} = \frac{3V}{S} \frac{a}{\chi_{\text{eff}}} = c_{\text{geo}} \frac{a^2}{\chi_{\text{eff}}}$$

- This could be called the *intuititve interpretation* of  $\tau_E$ .
  - However, different transport/loss mechanisms affect the plasma simultaneously at different locations. Isn't it just bull completely oversimplifield?

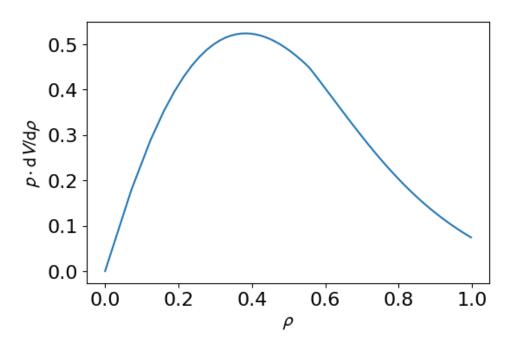

# A (crude) model for global transport II

• While  $\tau_E$  is indeed a quantity averaging over very different phyics at different radii, it is strongly weighted towards half radius:

$$W_{\rm kin} = \frac{3}{2} \cdot \int p(\rho) \frac{\mathrm{d}V}{\mathrm{d}\rho} \mathrm{d}\rho$$

 $\rightarrow$  Without drastic changes in the center or edge of the plasma (sudden profile peaking, high radiation,...),  $\tau_E$  may be indicative for the transport around half radius. But this needs to be confirmed from case to case.

# A (crude) model for global transport II

• While  $\tau_E$  is indeed a quantity averaging over very different phyics at different radii, it is strongly weighted towards half radius:

$$W_{\rm kin} = \frac{3}{2} \cdot \int p(\rho) \frac{{\rm d}V}{{\rm d}\rho} {\rm d}\rho \qquad 0.5 \\ 0.4 \\ 0.0 \\ 0.0 \\ 0.0 \\ 0.2 \\ 0.4 \\ 0.6 \\ 0.8 \\ 1.0 \\ 0.$$

 $\rightarrow$  Without drastic changes in the center or edge of the plasma (sudden profile peaking, high radiation,...),  $\tau_E$  may be indicative for the transport around half radius. But this needs to be confirmed from case to case.

# Before we go on, let's check it!

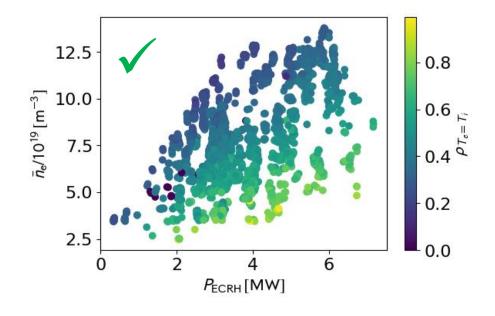

• The intuititve interpretation is applicable if at  $\rho=0.5$ :  $T_e=T_i$  and if the  $\tau_F$  has the same n,P-scaling as  $1/\chi_{eff}$ .

$$\tau_{\rm E} = \frac{3V}{S} \frac{a}{\chi_{\rm eff}} = c_{\rm geo} \frac{a^2}{\chi_{\rm eff}}$$

$$\chi_{\mathrm{eff}} pprox rac{aP}{2Sar{n}ar{T}}$$

	α (n <sup>α</sup> )	β (P <sup>β</sup> )
$\tau_{_{E}}$	0.22	-0.48
$1/\chi_{\rm eff}$	0.07	-0.38

 $\rightarrow$  The intuitive interpretation seems to be (somewhat) justified.  $\chi_{eff}$  also shows a weak density scaling, if any (ISS04:  $\alpha = 0.54$ ). But why?!

## Losses?

- Radiation losses are high, but radiation front usually outside the confined plasma (cf. Zhang et al, EPS 2018)
  - Weak density scaling already at  $n_e > 3-4 \cdot 10^{19} \text{ m}^{-3}$
- Charge exchange losses are estimated to be low (below 10 % of P<sub>FCRH</sub>)
  - Experimental verficiation outstanding

→ Losses may contribute to the weak density scaling, but it is unlikely that they are causing it.

# What would we expect?

- Best guess without any knowledge
  - Empirical cross-machine scaling ISS04

$$\tau_{\rm ISS04} = 0.134a^{2.28}R^{0.64}P^{-0.61}\bar{n}_{\rm e}^{0.54}B^{0.84}\iota_{2/3}^{0.41}$$

• ISSO4 is consistent with a Gyro-Bohm-like transport due to microinstabilities (coincidence not excluded!):  $\chi_{GB}^{\sim}$  T<sup>3/2</sup>

$$\chi_{\text{eff}} \propto \frac{P}{\bar{n}\bar{T}} \propto T^{3/2} \Rightarrow T \propto \left(\frac{P}{n}\right)^{2/5}$$

$$\Rightarrow \chi_{\text{eff}} \propto \left(\frac{P}{n}\right)^{3/5}$$

$$\Rightarrow \tau_{\text{E}} \propto \left(\frac{n}{P}\right)^{3/5}$$

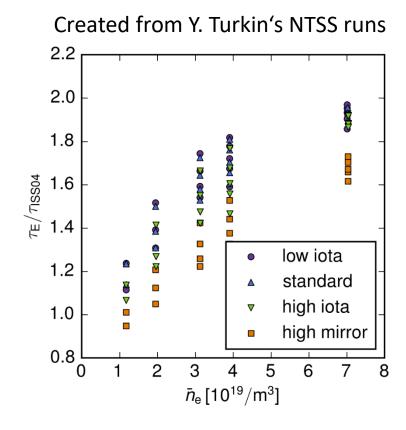

# What would we expect? II

- We can guess very accuratly, if the transport is dominated by NC
  - Using NTSS/DKES, predictive runs have been made assuming turbulence only plays a major role in the edge.
  - In those, the density dependence is not a simple power law, but it is stronger than in ISSO4.

→ This together with the observation that turbulence plays a major role in OP1.2 makes it **unlikely** that the weak density scaling is **a NC effect**.

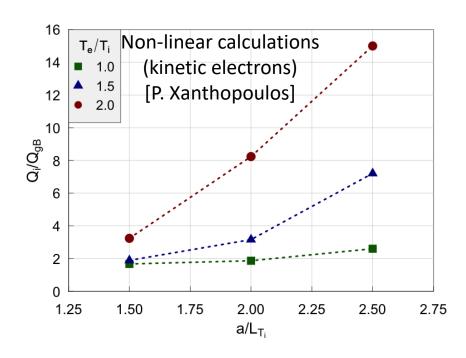

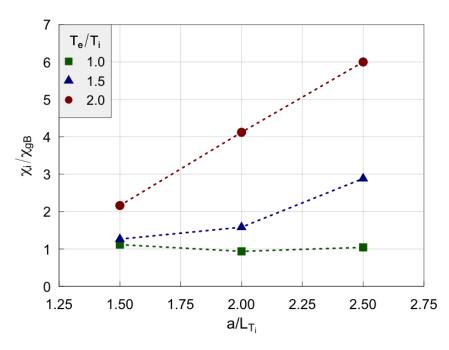

## **Turbulence**

- In the parameter space of OP1.2: Ion temperature clamped around 2 keV
  - Central ion temperature basically unchanged at  $n_e > 3.10^{19} \text{ m}^{-3}$  (coincidence?)
  - The clamping is currently thought to be caused by ITG turbulence.
  - Combined effect of a certain degree of stiffness of the ion transport and, more importantly, a strong increase of ITG-related transport with  $T_e/T_i$ .

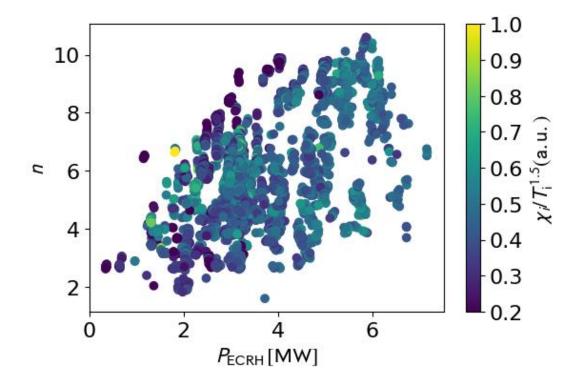

## **Observation**

 Indeed it seems that the ion heat diffusivity at half radius follows a gyro-Bohm scaling.

What if electrons and ions were independent?

#### electrons

$$P_{\rm ECRH}-P_{\rm ei}=-nS\chi_{\rm e}\nabla T_{\rm e}+\dots$$
 
$$\propto nT_{\rm e}^{5/2} \qquad {\rm We're~just~exploring,}$$
 ions 
$$P_{\rm ei}=-nS\chi_{\rm i}\nabla T_{\rm i}+\dots$$
 
$$\propto nT_{\rm i}^{5/2} \qquad \times nT_{\rm i}^{5/2}$$
 IF gyro-Bohm

Scaling of T<sub>e</sub>, T<sub>i</sub> (aussuming independence and gyro-Bohm):

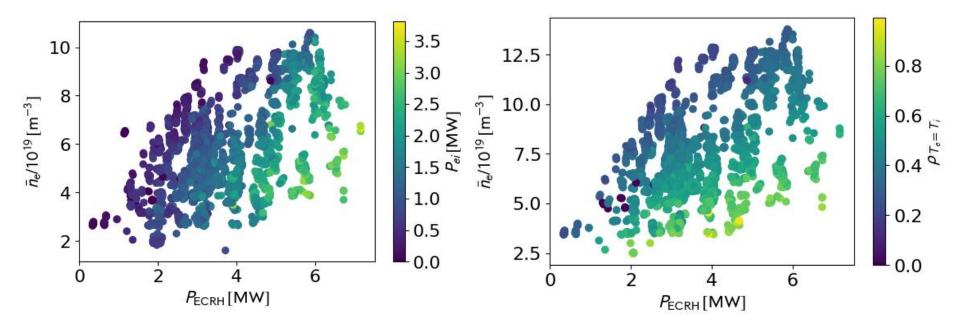

$$T_{
m e} \propto \left(rac{P_{
m ECRH} - P_{
m ei}}{n}
ight)^{2/5}$$
 
$$T_{
m i} \propto \left(rac{P_{
m ei}}{n}
ight)^{2/5}$$

## Interestingly, P<sub>ei</sub> is almost independent of the density

- Not neccessarily intuitive, since the transfer power increases with n<sup>2</sup>
- But T<sub>e</sub> = T<sub>i</sub> achieved at smaller radii ("transfer volume" decreases).
- Actually, it seems that P<sub>ei</sub> decreases very slightly with density (needs to be confirmed with latest profile versions).

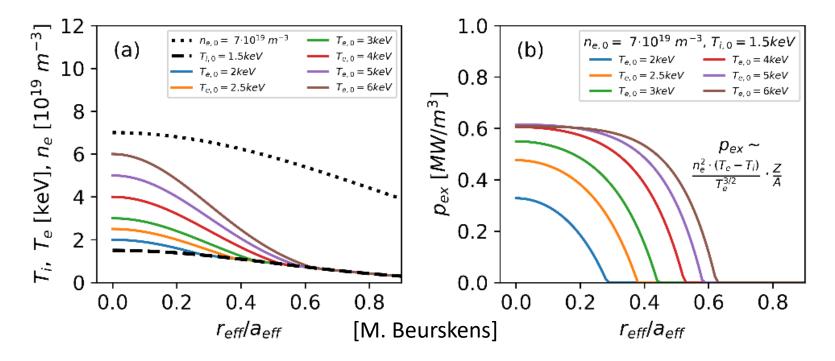

## Interestingly, P<sub>ei</sub> is almost independent of the density

- Not neccessarily intuitive, since the transfer power increases with n<sup>2</sup>
- But T<sub>e</sub> = T<sub>i</sub> achieved at smaller radii ("transfer volume" decreases).
- Actually, it seems that P<sub>ei</sub> decreases very slightly with density (needs to be confirmed with latest profile versions).

- Compare the scaling of T( $\rho$ =0.5) with hypothetical T<sub>e,GB</sub> and T<sub>i,GB</sub>
  - $T(\rho=0.5)$  shows a scaling much closer to  $T_{i,GB}$ .

$$P_{\rm ECRH} - P_{\rm ei} = -nS\chi_{\rm e}\nabla T_{\rm e} + \dots$$
  
  $\propto nT_{\rm e}^{5/2}$ 

$$P_{\rm ei} = -nS\chi_{\rm i}\nabla T_{\rm i} + \dots$$
$$\propto nT_{\rm i}^{5/2}$$

	α (n <sup>α</sup> )	β (Ρ <sup>β</sup> )
$T(\rho=0.5)$	-0.93	0.64
$T_{e,GB}$	-0.24	0.34
$T_{i,GB}$	-0.76	0.56

$$au_{\rm E} \propto \frac{1}{\chi_{\rm eff}} \propto \frac{nT}{P}$$

	α (n <sup>α</sup> )	β (P <sup>β</sup> )
$T(\rho=0.5)$	0.07	0.36
$T_{e,GB}$	0.52	0.57
$T_{i,GB}$	0.24	0.44
W7-X	0.22	0.48

### **Observation**

- The temperature at half-radius behaves as if it was completely determined by the ions with a gyro-Bohm-like transport.
  - At half radius, that seems to be in agreement with experimental data.
  - In a sense,  $P_{ei}$  seems to be the main factor determining  $\tau_E$  by propagating ist weak density scaling to  $T(\rho=0.5)$ .
  - Open question: Is the electron transport affected by this or only T<sub>e</sub>?

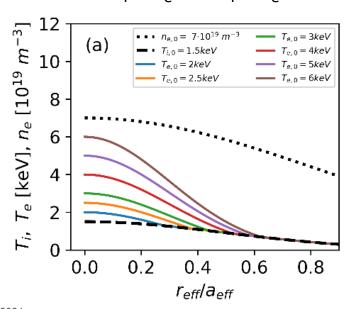

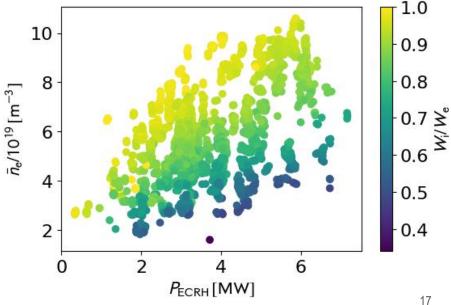

# **Summary**

- The energy confinement time in the basic ECRH plasmas of W7-X:
  - Seems to reflect transport and temperatures around half-radius.
  - The transfer power P<sub>ei</sub> seems to be a strong determining factor of both.
  - If that is true,  $\tau_E$  is influenced by the turbulence in the core in two ways: By setting the actual transport level and by the strong profile dependence of  $P_{ei}$  (n,  $T_e$  and  $T_i$ ).
  - The weak density scaling would then partly "just" describe how we go from W<sub>i</sub><W<sub>e</sub> to W<sub>i</sub>≈W<sub>e</sub> in the OP1.2b parameters space.

# **Happy Monday Speculation**

#### Why do we not see this in the ISS04?

- The stellarator database includes both ECRH and NBI plasmas.
- Some of the smaller experiments may have very low ion temperatures, showing very different physics.
- Maybe some other experiments actually show similar dependence, but these could get lost when comparing different machines with larger changes in the scaling parameters.

#### Is the weak density scaling an issue for fusion?

- Probably not, because a reactor with  $T_e > T_i$  would not be attractive (we would just not build that...). But then the scaling would look different.
- How? We do not know yet.
